Name: KEY
UT EID: _____

- Recall the He balloon that we described in class yesterday. The balloon was inflated at room pressure and room temperature. Imagine that we place the balloon in a very cold ice bath, and we bring the temperature of the balloon down to -5°C . Draw a "small particle" diagram of the balloon at room temperature. Then draw another "small particle" model diagram of the balloon at the lower temperature.

Since $PV = nRT$

n - constant

P - constant

R - constant

if $T \downarrow V$ must \downarrow

- How does the number density of the gas in the balloon at -5°C compare to the number density of the gas inside the balloon at room temperature. Please explain.

number density increases at lower T

Because $\frac{n}{V} = \frac{P}{RT}$ n constant so $\frac{1}{V}$ \uparrow
 $V \downarrow$

- How does the mass density of the gas in the balloon at -5°C compare to the mass density of the gas inside the balloon at room temperature. Please explain.

mass density increases at lower T

$$\text{mass density} = \text{molar mass} \times \frac{n}{V}$$

since number density increases with decreasing T , mass density will as well.
Same amount of gas spread over a smaller volume!
